

**ANNEX 1    KEY CATEGORIES**

**ANNEX 2    DETAILED DISCUSSION OF ACTIVITY DATA AND EMISSION FACTORS FOR ESTIMATING CO<sub>2</sub> EMISSIONS FROM FOSSIL FUEL COMBUSTION**

**ANNEX 3    CO<sub>2</sub> REFERENCE APPROACH AND COMPARISON WITH SECTORAL APPROACH, AND RELEVANT INFORMATION ON THE NATIONAL ENERGY BALANCE**

**ANNEX 4    ASSESSMENT OF COMPLETENESS AND (POTENTIAL) SOURCES AND SINKS OF GREENHOUSE GAS EMISSIONS AND REMOVALS EXCLUDED**

**ANNEX 5    UNCERTAINTY ANALYSIS**

**ANNEX 6    ARCHIVING - INVENTORY DATA RECORD SHEET, UNFCCC SEF APPLICATION**

**ANNEX 7    GHG EMISSION TREND**

**ANNEX 8    CO<sub>2</sub> EMISSION FACTORS, OXIDATION FACTORS AND NATIONAL NET CALORIFIC VALUES (needed for monitoring and reporting on CO<sub>2</sub> emission)**

## **ANNEX 1**

## **KEY CATEGORIES**

## A1.1. DESCRIPTION OF METHODOLOGY USED FOR IDENTIFYING KEY CATEGORIES

Key categories according to the IPCC Good Practice Guidance (IPCC, 2000) are those found in the accumulative 95% (Tier 1) or 90% (Tier 2) of the total annual emissions in the last reported year or belonging to the total trend, when ranked from contributing the largest to smallest share in annual total and in the trend. As originally designed it applied only to source categories. In addition, *Good Practice Guidance for Land Use, Land-Use Change and Forestry* expands the original approach to enable the identification of key categories that are either sources or sinks, which provides on how to identify key categories for the LULUCF. Therefore, the key category analysis was determined using both approaches:

- excluding LULUCF
- including LULUCF

Following the *Good Practice Guidelines*, Croatia undertook a key category analysis using Tier 1 and Tier 2 Level and Trend methods.

The IPCC and *Good Practice Guidance for Land Use, Land-Use Change and Forestry* also recommended which sources should be checked for their key category status, Table A1.1-1. Additionally, other sources of direct greenhouse gas emissions not listed in above mentioned guidance were added to the list, e.g. Solvent and Other Product Use.

### Level assessment

Level assessment involves an identification of categories as a key by calculating the proportion of emissions and removals in each category to the total emissions and removals. The calculated values of proportion are added from the category that accounts for the largest proportion, until the sum reaches 95% for Tier 1, 90% for Tier 2. Tier 1 level assessment uses emissions and removals from each category directly and Tier 2 level assessment analyzes the emissions and removals of each category, multiplied by the uncertainty (which is calculated in uncertainty analysis chapter) of each category.

### Trend Assessment

The purpose of the trend assessment is to identify categories that may not be large enough to be identified by the level assessment, but whose trend is significantly different from the trend of the overall inventory and should therefore receive particular attention.

The difference between the rate of change in emissions and removals in a category and the rate of change in total emissions and removals is calculated. The trend assessment is calculated by multiplying this value by the ratio of contribution of the relevant category to total emissions and removals. The calculated results, regarded as trend assessment values, are added from the category of which the proportion to the total of trend assessment values is the largest, until the total reaches 95% for Tier 1, 90% for Tier 2. At this point, these categories are defined as the key categories. Tier 2 trend assessment is calculated multiplying the Tier 1 trend assessment with uncertainty of each category (Table A5.2-1, Table A5.2-2).

Table A1.1-1: Categories Assessed in Key Category Analysis

Source Categories Assessed in Key Source Category Analysis	Direct GHG	Special Considerations
<b>ENERGY SECTOR</b>

N <sub>2</sub> O Emissions from Waste Incineration	N <sub>2</sub> O	

NO - source categories not occur in Croatia.

The reference to the summary overview for Key Categories 2012 in CRF tables is the Excel file HRV-2014-2012-v1.2, Table 7.

The level of disaggregation is in accordance with the suggested source categories split of the *Good Practice Guidance and Uncertainty Management in National Greenhouse Gas Inventories* and additionally, with the LULUCF category following the *Good Practice Guidance for Land Use, Land-Use Change and Forestry*.

Approach 2 has been done in defining and calculating key categories.

Comments relating to the Approach 2:

Using the aggregate emission factors for each sector, the differences between various types of coal and especially liquid fuel are not included, nor are the differences in the technology and the contribution of equipment for emission reduction. Therefore, the uncertainties associated with emission estimates of these gases are greater than estimates of CO<sub>2</sub> emissions from the fossil fuel combustion.

Uncertainty of N<sub>2</sub>O emission is estimated to factor 2 (the emission could be twice larger or smaller than the estimated one).

Because of the high uncertainties (200%) for categories Fuel Combustion - Stationary Sources (N<sub>2</sub>O) and Mobile Combustion - Road Vehicles (N<sub>2</sub>O), they were calculated as key categories.

(Table A1.2-7: Level Assessment - Tier 2 (Excluding LULUCF)-1990) ,(Table A1.2-9: Key categories analysis – Trend Assessment - Tier 2 (Excluding LULUCF)-2012), (Table A1.2-11: Key categories analysis – Level Assessment - Tier 2 (Excluding LULUCF)-2012), (Table A1.2-8: Key categories analysis – Level Assessment - Tier 2 (Including LULUCF)-1990) and ( Table A1.2-12: Key categories analysis – Trend Assessment - Tier 2 (Including LULUCF)-2012).

The GHG emissions from thermal power plants and public cogeneration plants, for the whole period (from 1990 to 2012), were calculated using more detailed Tier 2 approach. Tier 2 approach is based on bottom-up fuel consumption data from every boiler or gas turbine in plant. There were available data about monthly fuel

consumption and detailed fuel characteristics data (net calorific value, sulphur and ash content...). Every plant also has the equipment for continual measurements of SO<sub>2</sub>, NO<sub>x</sub>, CO and particulates emission.

For estimation of CO<sub>2</sub> emissions, default IPCC emission factors were used, while emission factors for CH<sub>4</sub> and N<sub>2</sub>O are based on technology type and configuration (Tier 2). The results of GHG emission calculation, using more detailed approach are presented in tables A2-2 and A2-3 for the 1990, 2000, 2005 and for period 2008-2012, on aggregated level. The GHG emissions on plant level, for the year 2012, are given in the Table A2-4.

Table A2-4: The GHG emissions from TPPs and PCPs (Tier 2), year 2011

## **ANNEX 4**

### **ASSESSMENT OF COMPLETENESS AND (POTENTIAL) SOURCES AND SINKS OF GREENHOUSE GAS EMISSIONS AND REMOVALS EXCLUDED**

Table A4-1 shows source/sink categories of GHGs that are not estimated in the Croatian GHG inventory, and the explanations for those categories being omitted. This table is taken from the CRF Table9a.

*Table A4-1: GHGs and source/sink categories not considered in the Croatian GHG inventory*

GHG	Sector <sup>(2)</sup>	Source/sink category <sup>(2)</sup>	Explanation
Carbon	5 LULUCF	5.A.2.5 Other Land converted to Forest Land	Explanation provided in LULUCF Chapter 7.2.4.2
Carbon	5 LULUCF	5.D.1 5.D.1 Wetlands remaining Wetlands	No sufficient data for estimates
Carbon	5 LULUCF	5.E.1 5.E.1 Settlements remaining Settlements	No sufficient data for estimation
Carbon	5 LULUCF	5.A.2.5 Other Land converted to Forest Land	Explanation provided in LULUCF Chapter 7.2.4.2
Carbon	5 LULUCF	5.D.1 5.D.1 Wetlands remaining Wetlands	No sufficient data for estimates
Carbon	5 LULUCF	5.E.1 5.E.1 Settlements remaining Settlements	No sufficient data for estimation
Carbon	5 LULUCF	5.A.2.5 Other Land converted to Forest Land	Explanation provided in LULUCF Chapter 7.2.4.2
Carbon	5 LULUCF	5.D.1 5.D.1 Wetlands remaining Wetlands	No sufficient data for estimates
Carbon	5 LULUCF	5.E.1 5.E.1 Settlements remaining Settlements	No sufficient data for estimation
Carbon	5 LULUCF	5.D.1 5.D.1 Wetlands remaining Wetlands	No sufficient data for estimates
Carbon	5 LULUCF	5.E.1 5.E.1 Settlements remaining Settlements	No sufficient data for estimation
Carbon	5 LULUCF	5.A.2.5 Other Land converted to Forest Land	Explanation provided in LULUCF Chapter 7.2.4.2
CH4	2 Industrial Processes	2.A.7.1 Glass Production	The IPCC Guidelines do not provide methodology for the calculation of CH4 emission.
CH4	2 Industrial Processes	2.C.1.1 Steel	The IPCC Guidelines do not provide methodology for the calculation of CH4 emission.
CH4	2 Industrial Processes	2.B.5 Sulphuric acid production	IPCC Guidelines do not provide methodology for the calculation of CH4 emission.
CH4	5 LULUCF	5.G Harvested Wood Products	parties do not have to prepare estimation for this category
CH4	6 Waste	6.C.2 Incineration of hospital wastes	IPCC Guidelines do not provide default emission factor for CH4 emission calculation from incineration of clinical waste. There is no national information on these data. Information on type of incineration technology is lacking.
CO2	2 Industrial Processes	2.A.5 Asphalt Roofing	IPCC Guidelines do not provide methodology for the calculation of CO2 emission.
CO2	2 Industrial Processes	2.A.6 Road Paving with Asphalt	The IPCC Guidelines do not provide methodology for the calculation of CO2 emission.

GHG	Sector <sup>(2)</sup>	Source/sink category <sup>(2)</sup>	Explanation
CO2	2 Industrial Processes	2.D.2 Food and Drink	CO2 from Food and Drink Production (e.g. gasification of water) can be of biogenic or non-biogenic origin. Only information on CO2 emission of non-biogenic origin should be reported.
CO2	2 Industrial Processes	2.B.5 Sulphuric acid production	IPCC Guidelines do not provide methodology for the calculation of CO2 emission.
CO2	5 LULUCF	5.G Harvested Wood Products	parties do not have to prepare estimation for this category
N2O	2 Industrial Processes	2.A.7.1 Glass Production	The IPCC Guidelines do not provide methodology for the calculation of N2O emission.
N2O	2 Industrial Processes	2.B.5 Sulphuric acid production	IPCC Guidelines do not provide methodology for the calculation of N2O emission.
N2O	3 Solvent and Other Product Use	3.B Degreasing and Dry Cleaning	IPCC Guidelines do not provide methodology for the calculation of N2O emission from Degreasing and Dry Cleaning.
N2O	3 Solvent and Other Product Use	3.D.5 Other Solvent Use (SNAP 0604)	IPCC Guidelines do not provide methodology for the calculation of N2O emission.
N2O	5 LULUCF	5.G Harvested Wood Products	Parties do not have to prepare estimation for this category
N2O	6 Waste	6.C.2 Incineration of hospital wastes	IPCC Guidelines do not provide default emission factor for N2O emission calculation from incineration of clinical waste. There is no national information on these data. Information on type of incineration technology is lacking.

## **ANNEX 5**

### **UNCERTAINTY ANALYSIS**

## A.5. METHODOLOGY FOR UNCERTAINTY ANALYSIS

Uncertainty estimates are calculated using two methods: Approach 1 (error propagation) and Approach 2 (Monte Carlo simulation). Use of the terminology Approach 1 and Approach 2 follows that defined in the IPCC's General Guidance and Reporting: 2006 IPCC Guidelines for National Greenhouse gas *Inventories* (2006 Guidelines) and 2000 IPCC Good Practice Guidance and Uncertainty Management in National Greenhouse Gas Inventories (2000 GPG).

The Monte Carlo method was reviewed and revised in this submission, taking into account guidance from the 2006 Good Practice Guidance (IPCC, 2006). It will be discussed later in the chapter.

Uncertainty analysis using Approach 2 method was calculated for all key sources, those which represent more than 95% of the total annual emissions in the last reported year or belonging to the total trend, when ranked from contributing the largest to smallest share in annual total and in the trend.

Approach 2 method was calculated only for key sources because the analysis is very detail and because of lack of data for each source category, that are needed to determine uncertainty of input data; which implies the determination of appropriate distribution of input parameters.

Categories that were included in the model are those that were calculated for key sources using level assessment or trend assessment.

Sources that are included in the uncertainty model contribute to total emissions more than 97%.

Uncertainty estimates were calculated in Excel spreadsheet application. Data have been divided into six sectors according to modus how the inventory work is organized (Energy, Industrial Processes, Solvent and Other Product Use, Agriculture, Land Use, Land-Use Change and Forestry and Waste).

Every sector has been divided into sources. Each source was evaluated regarding uncertainties (%) on activity data (AD), emission factors (EF) or direct emissions (EM).

### A.5.1. ESTIMATION OF UNCERTAINTY BY MONTE CARLO SIMULATION (APPROACH 2)

#### A.5.1.1. Overview of the method

The Monte Carlo analysis is suitable for detailed category-by-category assessment of uncertainty, particularly where uncertainties are large, distribution is non-normal, distribution functions are complex and/or there are correlations between some of the activity sets, emissions factors, or both.

The principle of Monte Carlo analysis is to select random values of emission factor, activity data and other estimation parameters from within their individual probability density functions, and to calculate the corresponding emission values.

This procedure is repeated many times, using a computer, and the results of each calculation run build up the overall emission probability density function.

Monte Carlo analysis can be performed at the category level, for aggregations of categories or for the inventory as a whole.

Detailed procedure:

- A probability distribution function (PDF) was allocated to each emission factor and activity data. The PDFs were mostly normal, log-normal or triangle. The parameters of the PDFs were set by analysing the available data on emission factors and activity data or by expert judgement.  
If there was a lack of data for some emission source, associated uncertainties were extracted from the IPCC guidelines which imply that default uncertainty parameters were set.
- Using the software tool @RISK 5.7, each PDF was sampled 10,000 times and the emission calculations performed to produce a converged output distribution.
- The uncertainty in the trend between 1990 and the latest reported year, according to gas, was also estimated.

#### A.5.1.2. Uncertainty distributions

##### Distributions

All of the input parameters in inventory are modelled using normal (97%), triangle and log-normal distributions.

##### Correlations

The Monte Carlo model contains a number of correlations. Omitting these correlations would lead to the uncertainties being underestimated.

The trend uncertainty in the Monte Carlo model is particularly sensitive to some correlations.

##### Activity data and emission factor uncertainty

If for activity data or emission factor uncertainty default value from IPCC guidance was used, average value from range of given uncertainty was set.

For some pollutants and source categories, no information on uncertainty ranges were available in the Guideline so uncertainty estimates derive from expert judgment or were taken from other inventories (Japan).

### Uncertainty in the emissions excluding LULUCF

The uncertainty of the key source emission was estimated at -15% to 16% in year 2012 and -13% to +14% in year 1990 (bottom of the Table A5.1-2).

The central estimate of CO<sub>2</sub>-eq emissions in 2012 was estimated at 26,385.288 Gg CO<sub>2</sub>-eq.

The central estimate of CO<sub>2</sub>-eq emissions in 1990 was estimated at 31,679.780 Gg CO<sub>2</sub>-eq.

All key sources (level/trend) represent 98.11% (25,885.572 Gg CO<sub>2</sub>-eq) of the total inventory emission for the year 2012, and 97.99% (31,042.037 Gg CO<sub>2</sub>-eq) for the year 1990.

Monte Carlo analysis shows that with a certainty of 95% we can say that the total emissions of all key categories for the year 2012 (25,885.572 Gg CO<sub>2</sub>-eq) varies between 22,007.756 Gg CO<sub>2</sub>-eq (2.5% percentile) and 30,052.779 Gg CO<sub>2</sub>-eq (97.5% percentile).

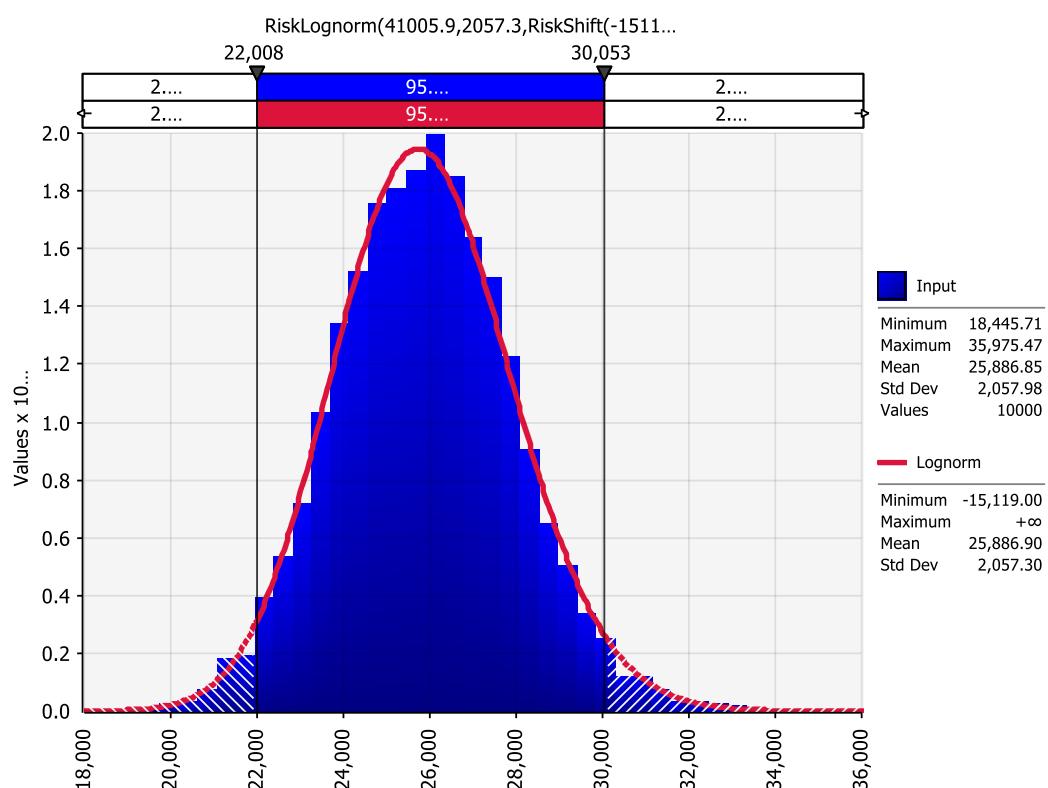

Figure A5.1-1: Distribution of total CO<sub>2</sub> emission for year 2012

Figure A5.1-1 shows the distribution of total CO<sub>2</sub> emission for year 2012 with a corresponding probability density function (red line) that best matches the simulation results.

Monte Carlo analysis shows that with a certainty of 95% we can say that the total emissions of all key categories for the year 1990 (31,042.037 Gg CO<sub>2</sub>-eq) varies between 27,099.595 Gg CO<sub>2</sub>-eq (2.5% percentile) and 35,389.825 Gg CO<sub>2</sub>-eq (97.5% percentile).

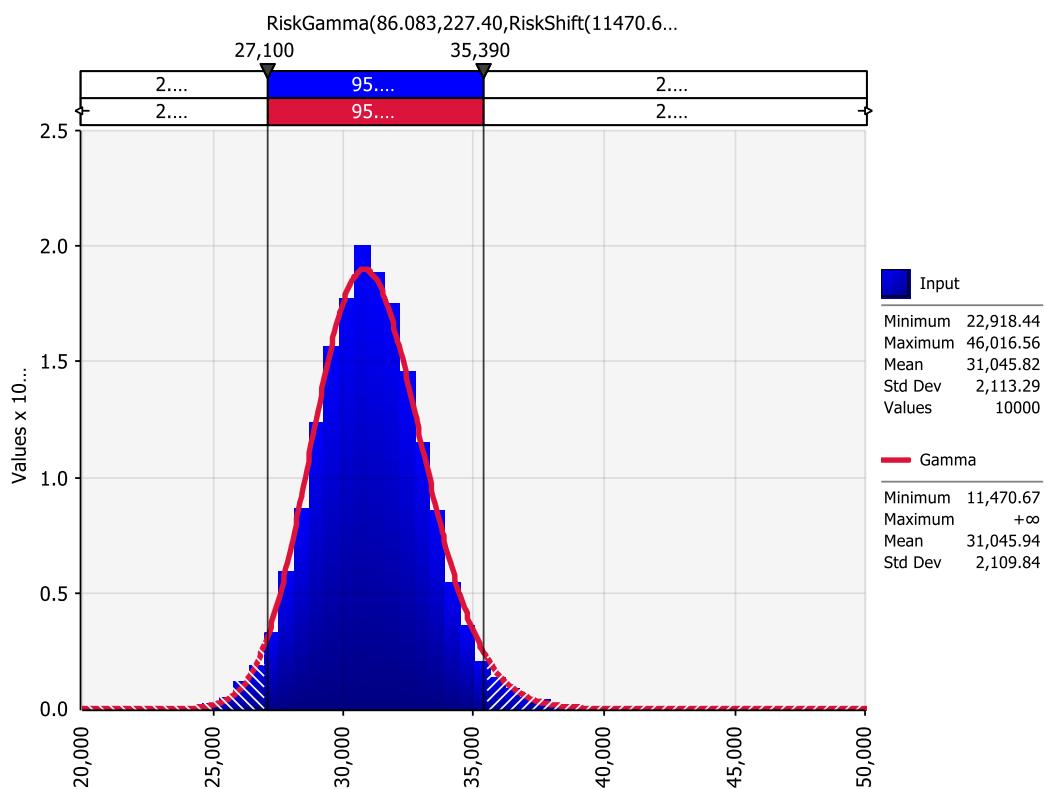

Figure A5.1-2: Distribution of total CO<sub>2</sub> emission for year 1990

Figure A5.1-2 shows the distribution of total CO<sub>2</sub> emission for year 1990 with a corresponding probability density function (red line) that best matches the simulation results.

### Uncertainty in the trend excluding LULUCF

The uncertainty in the trend between 1990 and 2012 was estimated. In running this simulation it was necessary to make assumptions about the degree of correlation between sources in year 1990 and 2012.

If source emission factors are correlated this will have the effect of reducing the trend uncertainty.

The assumptions were as follows:

- Activity data are not correlated;
- Emission factors of some similar fuels are correlated;
- Emission factors for agriculture are all default and the same for 1990 and 2012 for all the activities except for: CH<sub>4</sub> emissions from enteric fermentation (dairy cattle). They are separately calculated which implies that they are different every year;

- Energy emission factors are not correlated;
- In Industry sector emission factors for categories Nitric Acid Production and CH<sub>4</sub> Production of Chemicals are correlated for both years, but for categories CO<sub>2</sub> Emissions from Cement Production and CO<sub>2</sub> Emissions from Lime Production are not correlated;
- In Solvent sector there is no correlation between years;
- In Waste sector in category Solid Waste Disposal there isn't correlation between years and in category Waste Water Handling there is correlation.

The trend in the inventory is estimated for each category and for the total summary emission (all categories included) with the following formula:

$$\text{Mean Trend (\%)} = \left( \frac{\text{Year emissions} - \text{Base year emissions}}{\text{Base year emissions}} \right) \cdot 100 .$$

For the 'total' at the foot of the Table A5.1-2, the overall uncertainty in the trend for the entire key source activities is given.

The Inventory trend is -16.31%, and the 95% probability range of the trend is -31.06% (2.5% percentile) to 0.31% (97.5% percentile), so the uncertainty in trend is from -14.45% to 16.92% with respect to the base year emissions.

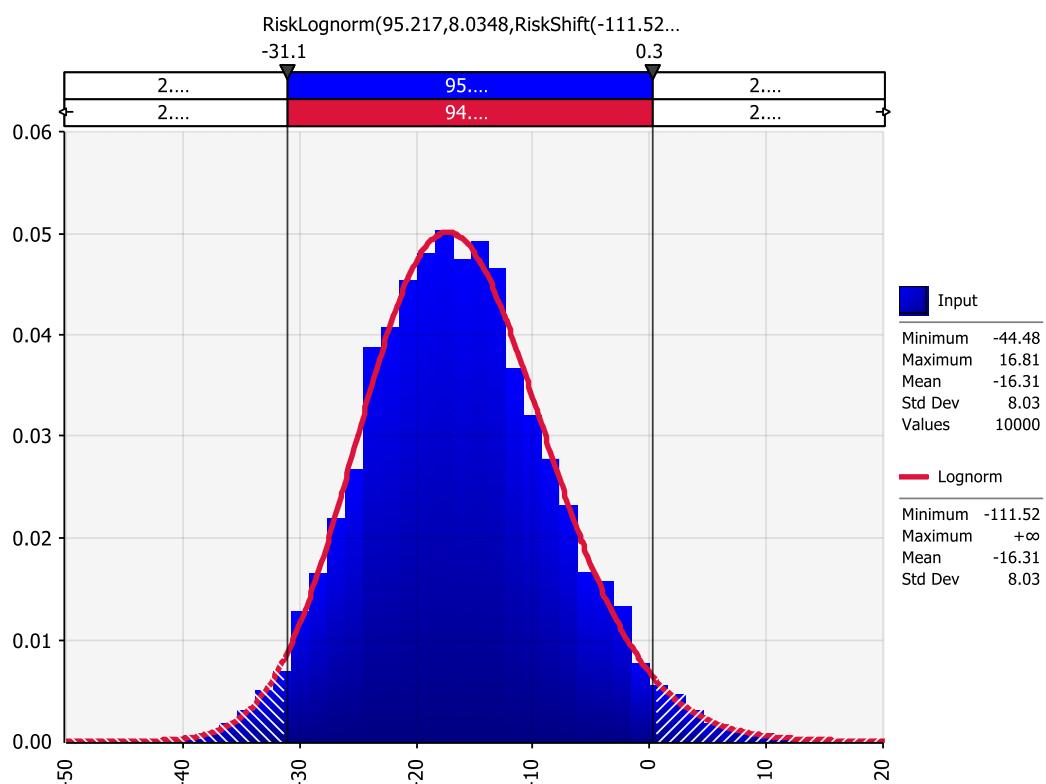

Figure A5.1-3: Distribution of trend for year 2012 respect to year 1990

Figure A5.1-3: shows the distribution of trend for year 2012 respect to year 1990 with a corresponding probability density function (red line) that best matches the simulation results.

### Uncertainty in the emissions including LULUCF

The uncertainty of the key source emission was estimated at -38% to +39% in year 2012 and -25% to +27% in year 1990 (bottom of the Table A5.1-3).

The central estimate of CO<sub>2</sub>-eq emissions in 2012 was estimated at 20,494.449 Gg CO<sub>2</sub>-eq including LULUCF. The central estimate of CO<sub>2</sub>-eq emissions in 1990 was estimated at 25,169.532 Gg CO<sub>2</sub>-eq including LULUCF.

All key sources (level/trend) represent 96.50% (19,776.556 Gg CO<sub>2</sub>-eq) of the total inventory emission for the year 2012, and 97.01% (24,417.582 Gg CO<sub>2</sub>-eq) for the year 1990.

Monte Carlo analysis shows that with a certainty of 95% we can say that the total emissions of all key categories for the year 2012 (19,776.556 Gg CO<sub>2</sub>-eq) varies between 12,249.754 Gg CO<sub>2</sub>-eq (2.5% percentile) and 27,479.424 Gg CO<sub>2</sub>-eq (97.5% percentile).

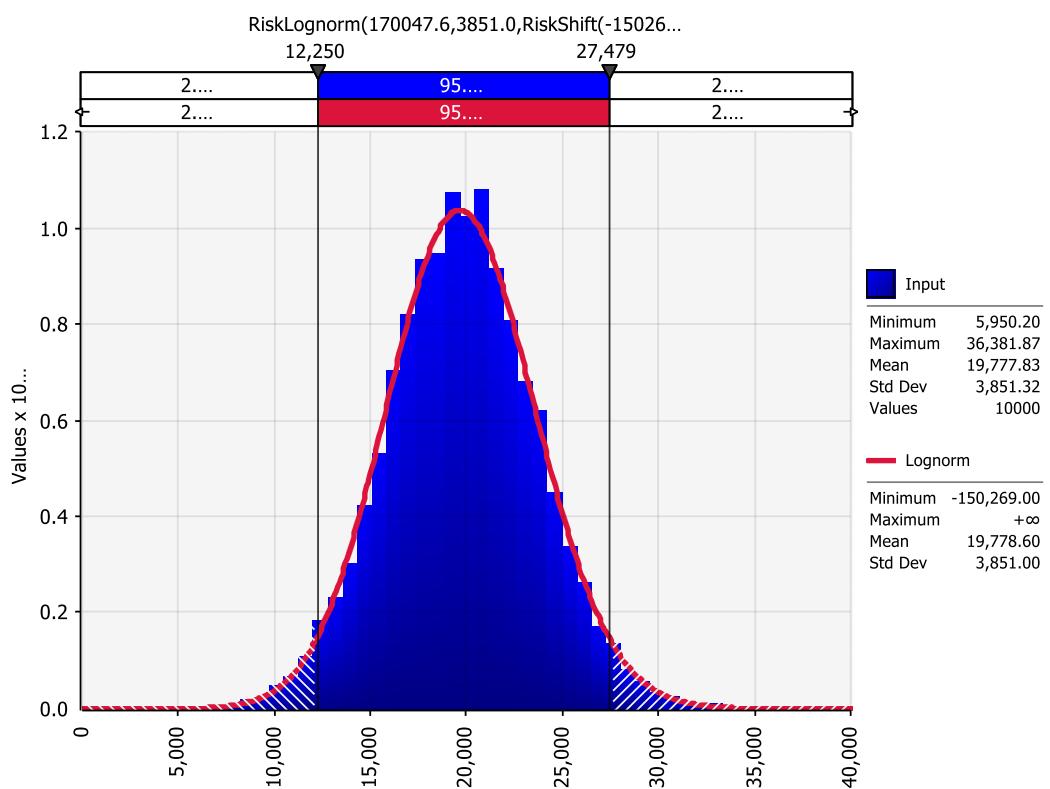

Figure A5.1-4: Distribution of total CO<sub>2</sub> emission for year 2012

Figure A5.1-4 shows the distribution of total CO<sub>2</sub> emission for year 2012 with a corresponding probability density function (red line) that best matches the simulation results.

Monte Carlo analysis shows that with a certainty of 95% we can say that the total emissions of all key categories for the year 1990 (24,417.582 Gg CO<sub>2</sub>-eq) varies between 18,250.657 Gg CO<sub>2</sub>-eq (2.5% percentile) and 30,953.109 Gg CO<sub>2</sub>-eq (97.5% percentile).

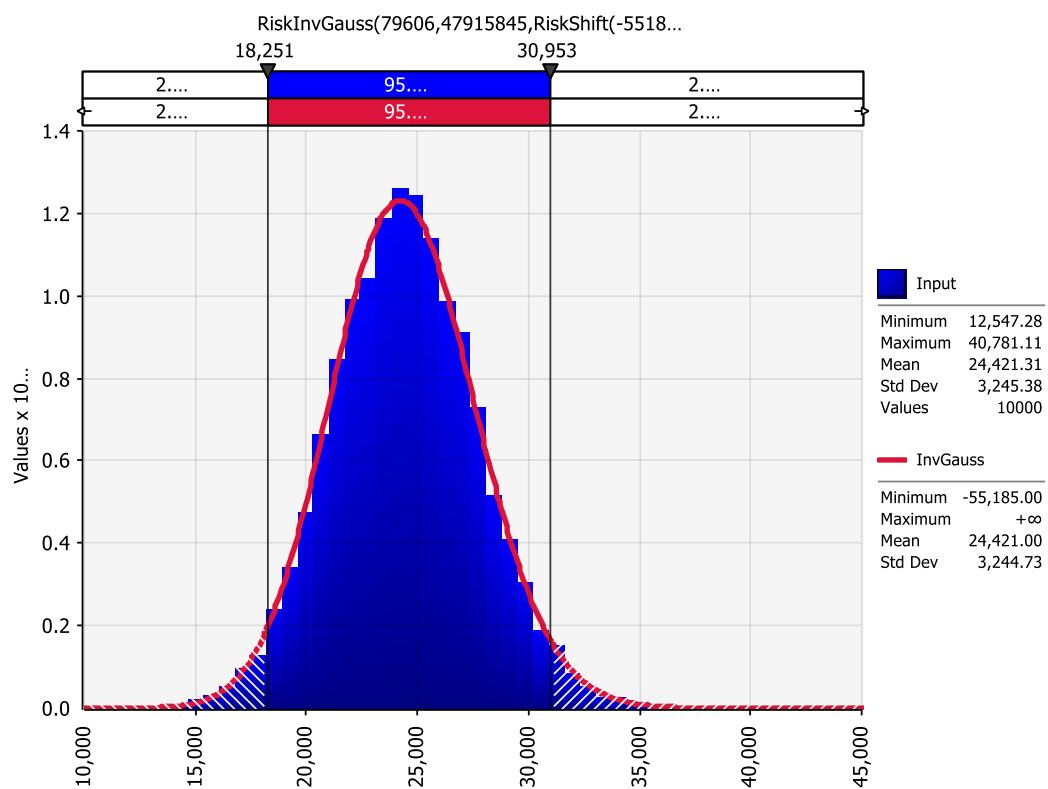

Figure A5.1-5: Distribution of total CO<sub>2</sub> emission for year 1990

Figure A5.1-5 shows the distribution of total CO<sub>2</sub> emission for year 1990 with a corresponding probability density function (red line) that best matches the simulation results.

#### Uncertainty in the trend including LULUCF

The Inventory trend is -14.63%, and the 95% probability range of the trend is -51.42% (2.5% percentile) to 24.10% (97.5% percentile), so the uncertainty in trend is from -32.41% to 43.11% with respect to the base year emissions.

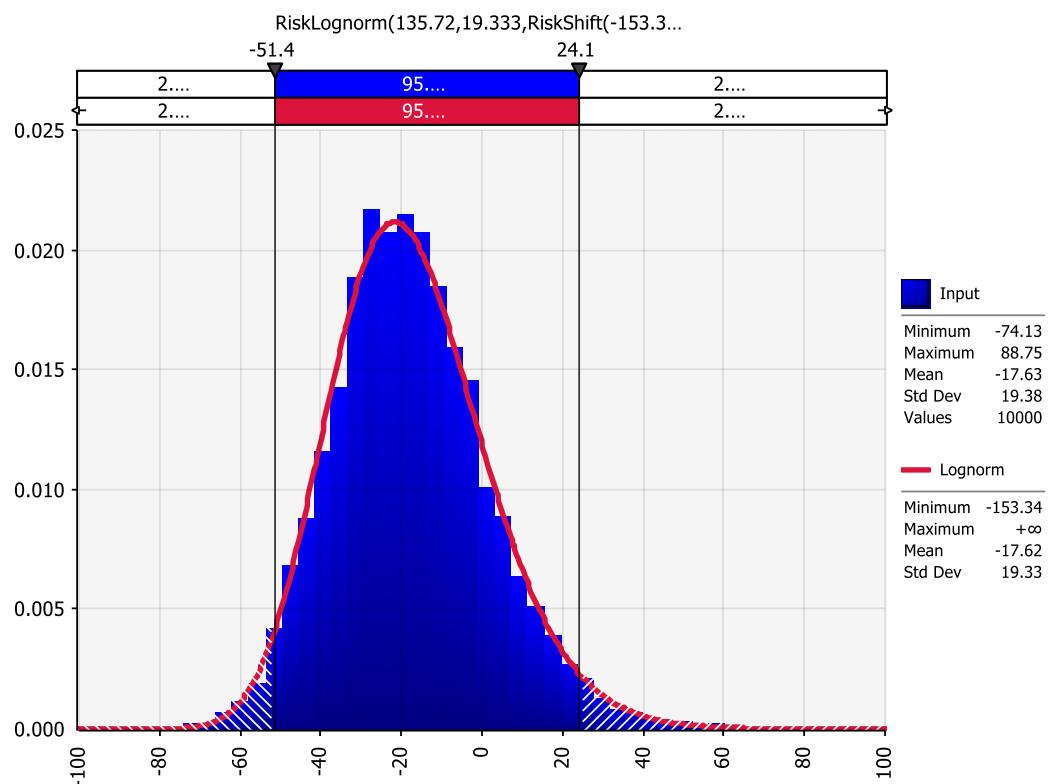

Figure A5.1-6: Distribution of trend for year 2012 respect to year 1990

Figure A5.1-6: shows the distribution of trend for year 2012 respect to year 1990 with a corresponding probability density function (red line) that best matches the simulation results.

Approach and Comments:

1. Manufacturing Industries and Construction Total (1990-2000) is emission category which existed till 2000 year; afterwards its emission was included in other source categories.
2. Fugitive Emissions from Oil and Gas Operations: for this category wasn't enough data to calculate combine uncertainty with Monte-Carlo method, therefore combine uncertainty data from tier 1 method was implied in model.
3. CO<sub>2</sub> Emissions from Natural Gas Scrubbing: for this category wasn't enough data to calculate combine uncertainty with Monte-Carlo method, therefore combine uncertainty data from tier 1 method was implied in model.
4. A more complex method for estimation of uncertainties is used, and therefore activity data and emission factor uncertainties are left blank. Only combined uncertainty and trend uncertainty is shown in model.
5. Trend not calculated, when base year or year t emissions are zero or included elsewhere.
6. Emission is included in category Other Manufacturing Industries and Construction Total (1990-2000). There were no disaggregated data till 2000.
7. Because of the existence of variables in model with triangle distribution there is a slight deviation of emission in model and in CRF-REPORTER  
\*Left value is "real" value from crf reporter and right value is mean value of variable with its distribution
8. Combined uncertainty was used in Monte Carlo simulation for LULUCF sector

## A.5.2. ESTIMATION OF UNCERTAINTIES USING AN ERROR PROPAGATION APPROACH (APPROACH 1)

### A.5.2.1. Overview of the method

In the Approach 1, an uncertainty in an emission can be propagated from uncertainties in the activity data and the emission factor through the error propagation equation (Mandel 1984, Belington and Robinson 1992).

This method is presented in the current 1996 *IPCC Guidelines for National Greenhouse Gas Inventories* (officially in use), where the conditions imposed for use of the method are:

- The uncertainties are relatively small, the standard deviation divided by the mean (coefficient of variation) value being less than 0.3;
- Input parameters (emission factor, activity data) have Gaussian (normal) distributions. Uncertainty is symmetric with respect to the mean value. The length of the range from mean to upper larger value (97.5% percentile) is equal to the length of the range from mean to lower, smaller value (2.5% percentile).
- The correlation between the input data in model between years doesn't exist.

Under these conditions, the uncertainty calculated for the emission rate is appropriate.

Summary uncertainty value is calculated for all emission sources and separately for key source categories that were included in Monte-Carlo analysis (Tier 2). The results of the error propagation approach are shown in Tables A5.2-1 and A5.2-2 (gray shaded area).

The uncertainties used and calculated in the error propagation approach are not exactly the same as those used in the Monte Carlo Simulation since the error propagation source categorisation is far less detailed.

However, the values used were chosen to agree approximately with those used in the Monte Carlo Simulation.

### A.5.2.2. Correlation assumptions

Calculation of trend uncertainty using tier 1 method is based on the essential assumption that the input uncertainty of emission factors and activity data for 1990 and 2011 are equal. With that assumption, we can use the default 3.2. Table from 2006 *IPCC Guidelines*. Formulas in columns K and L are used as they are given. That kind of assumption is not expected in real life.

Uncertainties for 1990 and 2011 are not equal (activity data uncertainty, emission factor uncertainty).

Therefore, the formulas in columns K, L of the 3.2. Table should change the default format, according to existence of new different activity data and emission factor uncertainty into:

## Column K

Under the assumption that the same emission factor is used in both years and the actual emission factors are fully correlated, the percent error introduced by it is equal in both years. Therefore the formula for the uncertainty introduced on the trend by the emission factor is:

$$K = I * F = \text{sensitivity A} * \text{uncertainty of emission factor}$$

In case no correlation between emission factors is assumed, sensitivity B should be used and the result needs to be increased by  $\sqrt{\text{uncertainty (emission factor, base year)}^2 + \text{uncertainty (emission factor, year t)}^2}$ .

$$J = \text{sensitivity B}$$

$$K = J * \sqrt{\text{uncertainty (emission factor, base year)}^2 + \text{uncertainty (emission factor, year t)}^2}$$

## Column L

The trend is the difference between the emissions in the base year and in the year t. Therefore the uncertainty of the activity data of the base year and year t has to be taken into account.

Since activity data in both years are assumed to be independent, Column L equals:

$$L = \text{sensitivity B} * \text{combined uncertainty of activity data of both years}$$

$$= J * \sqrt{\text{uncertainty (activity data, base year)}^2 + \text{uncertainty (activity data, year t)}^2}$$

In case correlation between activity data is assumed what is not expected in real life, sensitivity A should be used and the final formula is:  $L = I * E$ .

Two columns (O and P) reflecting uncertainty of emission factors and activity data for year 1990 have been added in Table A5.2-1 and Table A5.2-2.

Activity data and emission factor uncertainty in Table A5.2-1, Table A5.2-2 for the key source activities that have been checked and calculated in detail using Monte Carlo analysis have been updated.

IPCC Source category Mobile Combustion: Agriculture/Forestry/Fishing has been changed to Combustion: Agriculture/Forestry/Fishing because the emission value includes both mobile and stationary sources.

## Emissions uncertainty

The error propagation analysis, excluding LULUCF emissions, shows an uncertainty of +/- 15.17% in the combined GWP total emission in 2012, the latest reported year in this inventory.

The error propagation analysis, including LULUCF emissions, shows an uncertainty of +/- 35.86% in the combined GWP total emission in 2012, the latest reported year in this inventory.

### **Uncertainty in the Trend**

The analysis, excluding LULUCF emissions, estimates an uncertainty of +/- 16.84% in the trend between the year 1990 and 2012, the latest reported year in this inventory.

The analysis, including LULUCF emissions, estimates an uncertainty of +/- 37.73% in the trend between the year 1990 and 2012, the latest reported year in this inventory.

### A.5.3 COMPARISON OF UNCERTAINTIES FROM THE ERROR PROPAGATION AND MONTE CARLO ANALYSES

Where the conditions for applicability are met (relatively low uncertainty, no correlation between sources except those dealt with explicitly by Approach 1, symmetrical distributions), Approach 1 and Approach 2 will give identical results.

Comparing the results of the error propagation approach, and the Monte Carlo estimation of uncertainty by simulation, is a useful quality control check on the behaviour of the Monte Carlo model.

The reason that the error propagation approach is used as a reference is because the mathematical approach to the error propagation approach has been defined and revised in the *2000 GPG* and the *2006 Guidelines*.

The implementation of uncertainty estimation by simulation cannot be prescriptive, and will depend on the Monte Carlo software a country chooses to use, how the country constructs its model, and the correlations included within that model. Therefore, there is a greater possibility of errors being introduced in the model used to estimate uncertainty by simulation.

If all the distributions in the Monte Carlo model were normal, and there were no correlations between sources, the estimated errors on the trend from the Monte Carlo model should be identical to those estimated by the error propagation approach.

In reality there will be correlations between sources, and some distributions are not normal and are heavily skewed. The error propagation approach does not account for the correlations, and so we might expect the trend uncertainty estimated by this method to be greater than obtained value.

The assumption of equivalence between the two methods relies on the fact that the distributions of individual uncertainties in the activity data and emissions factors in the two approaches are both normal. However, there are a number of lognormal and triangle distributions in the Monte Carlo model and the effects of these can not be fully reproduced in the error propagation model. These log-normal and triangle distributions will have the effect of increasing the uncertainty on the trend as the distributions are more skewed.

In Monte Carlo model used in this inventory, we were concentrated on uncertainties of key source categories that contribute 98.11% to total emissions. Key sources were considered because for them we had enough data to set model mathematically correct.

Model is set up so that each sector is divided in its category, and each category is divided into subcategories. Accordingly, uncertainty would not be underestimated. But, for some subcategories, uncertainty has been estimated on the basis of expert judgement or default uncertainty from the 2000 GPG has been used.

It is not expected that the central estimates from the two methods will be identical, which could be mathematically explained.

For some variables that could only assume negative values, in the Monte Carlo model for the definition of distribution of input parameters risk truncate function was used which resulted in slight change in mean value. The same slight change in mean value cause also log-normally distributed variables.

Total uncertainty for all key sources approximately amounts +/- 15-16% for error propagation approach and approach 2 (Monte Carlo) for year 2012 (excluding LULUCF).

Total uncertainty for all key sources approximately amounts +/- 36-39% for error propagation approach and approach 2 (Monte Carlo) for year 2012 (Including LULUCF).

Trend uncertainty (variability) using Monte Carlo simulation model is lower (approximately +/- 1%) than trend uncertainty using error propagation error. One of the reasons for that is because error propagation model deals with variables that have normal distributions, which implies symmetrical uncertainties for activity data and emission factor.

In Monte Carlo model some variables have log-normal or triangle distribution, which means that their value can vary plus infinite. Because of asymmetry of some input variables, it should not be expected for the final result (trend) to vary symmetrically. Also the uncertainty of input data for the year 1990 is not equal to the uncertainty for the year 2012, which also affects the changes in the variability of the trend.

Key category Indirect N<sub>2</sub>O Emissions from Nitrogen Used in Agriculture has created problems in defining the distribution functions which resulted in lower summary emission. It was due to the large asymmetry of variability of input values that are included in the calculation of emission of this source category.

We should point out also categories CO<sub>2</sub> Emissions from Ferroalloys Production, CO<sub>2</sub> Emissions from Aluminium Production and PFC Emissions from Aluminium production and few subcategories which emission was zero in year 2012, but in year 1990 they had emission which varied in accordance with the uncertainty of input parameters.

Environmental Pollution Register database and Landfill Inventory database (CEA)	
<b>METHOD:</b>	
bottom-up (see publications in original data source)	
<b>ADDITIONAL INTERCALCULATION:</b>	
Evaluation and compiling of data coming from original data source and adjusting to recommended Intergovernmental Panel on Climate Change (IPCC) methodology.	

<b>MODULE: WASTE</b>	
<b>SUBMODULE: METHANE EMISSIONS FROM SOLID WASTE DISPOSAL SITES</b>	
<b>WORKSHEET: 6-1</b>	<b>SHEET: 1 OF 1 CH<sub>4</sub> EMISSIONS</b>
<b>STEP: 1 TO 4</b>	<b>PAGE: 2 of 3</b>
<b>DATA ARCHIVATION:</b> Publications: Fundurulja, D., Mužinić, M. (2000) <i>Estimation of the Quantities of Municipal Solid Waste in the Republic of Croatia in the period 1990 – 1998 and 1998 – 2010.</i> Potočnik, V. (2000), Report: The basis for methane emission estimation in Croatia 1990-1998, B. Data on Municipal Solid Waste in Croatia 1990-1998 Environmental Pollution Register Database and Landfill Inventory Database, CEA	
<b>DATA GAPS:</b> MSW quantity estimation were in most cases gained by test weighing in order to estimate average volumes of waste delivered by vehicles and density of MSW. National classification of SWDSs is different from IPCC classification. Scarce data for DOC estimation.	
<b>SUGGESTION FOR THE FUTURE:</b> For the purposes of improvement activity data gathering from solid waste disposal activities it is necessary to improve quality of existing data:	
<ul style="list-style-type: none"> <li>• more accurate determination on waste quantities disposed to different types of SWDSs (managed, unmanaged deep and unmanaged shallow) – based on measurement/weighing or more accurate estimation</li> <li>• providing methodology to determine country-specific MSW composition and periodic analysis of waste composition at major landfills. It will be solved through the project of the CEA: <i>Creating a uniform methodology for the analysis of the composition of MSW, determine the average composition of MSW in the Republic of Croatia and the projection of the amount of MSW.</i></li> <li>• modification of Environmental Pollution Register and Landfill Inventory database regarding to MSW with additional information (provided on regular basis) on technical and environmental protection measures implemented at landfills, waste quantities disposed to different types of SWDS (managed, unmanaged deep and unmanaged shallow) and waste composition.</li> <li>• collecting the necessary data and information on organic industrial waste (including sludge from waste water treatment) disposed in SWDSs.</li> </ul> Adjustment of country-specific to IPCC SWDS classification for entire time series, in order to accurately estimate the MCF. Due to lack of adequate information, interpolation/extrapolation method has been applied for estimation of waste and landfills characteristics over a long period of time. It is necessary to improve the quality of existing data and to reconstruct historical data. More detailed background information related to the sources of AD and EFs are necessary in order to improve transparency. Research should be conducted in order to develop country-specific parameters for the first order decay method to increase the accuracy of the emission estimates. More information for uncertainty estimation is required, regarding more accurate and transparent uncertainty analysis.
